

OrderFlow AI

Multi-Tenant AI Order Intake Platform for Small & Medium Businesses

Full Product Blueprint · Architecture · Database Schema · API Design · Build Roadmap

Product	OrderFlow AI
Built By	ResurgeX Technologies
Document	v2.0 — Production Blueprint
Primary Channel	Inbound Phone Calls (Voice-First)
Secondary Channels	WhatsApp Text, WhatsApp Voice Note, SMS
Architecture	Multi-tenant SaaS — one platform, many businesses
Target MRR	\$5,000 (50 businesses @ \$99/month)
Pilot Customer	Provenos Deli, Connecticut

1. Executive Summary

OrderFlow AI is a voice-first, multi-channel order intake platform that replaces the human who answers the phone at small food businesses. A customer calls, an AI voice agent answers, takes the order including all customizations, confirms it, and the order appears instantly on a kitchen screen. The customer gets an SMS confirmation and a ready notification when their order is done. Staff focus on making food — not answering phones.

The platform is built multi-tenant from day one. Every business that signs up gets its own phone number, its own menu, its own kitchen display URL, and its own analytics. The operator (ResurgeX) manages all businesses from a single admin layer.

Primary insight: Deli customers order by phone. Phone calls are 80% of the volume. Everything else is secondary. Build the voice agent first.

The pilot is Provenos Deli in Connecticut. Once the system is live there and captured orders can be demonstrated on video, the same product is sold to every other deli, sandwich shop, bakery, and small restaurant in the region. The path to \$5K MRR is 50 businesses at \$99 per month — a realistic target within 6 months of launch.

2. The Problem

Small food businesses take a large share of their orders by phone every day. Every one of those calls requires a human employee to stop what they are doing, pick up the phone, accurately capture the order including any modifications, read it back, and pass it to the kitchen. The consequences of this model are well understood by any deli owner:

- Calls get missed during rush hour when staff are making food
- Orders get written down incorrectly, especially with customizations
- Staff time is split between food prep and phone duty, reducing both quality and speed
- There is no record of the call — if an order is lost, there is no way to recover it
- The business has no data on call volume, peak hours, or what customers actually ordered

Existing solutions do not solve this problem. Toast, Square, and similar POS systems are full restaurant management platforms — expensive, complex, and built for sit-down restaurants with table management and delivery logistics. They are overkill for a deli that simply needs to stop missing phone orders. DoorDash and Uber Eats solve a different problem entirely and take a significant commission on every order. There is no lightweight, affordable product designed specifically for the phone intake problem.

3. The Solution

3.1 What OrderFlow AI Does

OrderFlow AI is a multi-channel AI order intake system. It connects to a business's phone number and messaging channels, handles all inbound order contact automatically, and feeds every order into a single live kitchen display. The system works across four channels:

Inbound Phone Call	AI voice agent answers, greets caller by business name, takes the full order conversationally including all customizations and quantities, confirms the order, and ends the call. This is the primary channel.
WhatsApp Text	Customer sends a text message to the business WhatsApp number. AI chatbot responds, walks through the menu, captures customizations, confirms order.
WhatsApp Voice Note	Customer records and sends a voice note. System transcribes the audio using Whisper, extracts the order with GPT-4o, confirms back via text.
SMS	Customer sends an SMS. Same chatbot pipeline as WhatsApp. Confirmation sent back as SMS.

Regardless of which channel the order arrives through, the output is identical: a structured order object written to the database, a card appearing on the kitchen display, and a confirmation message sent to the customer. The staff never needs to know or care which channel the order came from.

3.2 The Kitchen Display

The kitchen display is a full-screen web application running on any tablet or monitor in the kitchen or at the front counter. It shows live order cards updating in real time. Each card displays the order number, every item with all customizations, the channel it came from, how many minutes ago it was placed, and a Done button. When staff press Done the card is archived and the customer receives an automated ready notification.

3.3 The Admin Portal

Each business has an admin portal where they can manage their menu, update business hours, view order history, review transcripts of calls, see analytics on call volume and peak hours, and manage staff accounts. The ResurgeX operator account can see and manage all businesses from a single interface.

4. Target Market

4.1 Primary Customer Profile

Any small to medium food business that receives inbound orders by phone and has a preparation area or kitchen. The customer is a business owner or manager who feels the daily pain of missed calls and wrong orders. They are not technical. They do not want to manage software — they want their phone answered.

Business Type	Why They Need This	Decision Maker
Deli / Sub Shop	High call volume, complex customizations, rush hour misses	Owner
Sandwich Shop	Lunch rush overwhelms staff, customizations are frequent	Owner / Manager
Bakery	Custom orders by phone, no system to track them	Owner
Butcher / Specialty Shop	Call-in orders for cuts and quantities, no digital trail	Owner
Small Local Restaurant	No online ordering, relies entirely on phone	Owner
Pizza Shop	High volume phone orders, customization-heavy	Owner / Manager
Pharmacy	Prescription call-ins and order status calls	Manager
Flower Shop	Custom orders, delivery instructions, event orders	Owner

4.2 Market Size

There are approximately 500,000 small food service businesses in the United States that do not use any form of automated order intake. At \$99 per month per business, capturing 1% of that market represents \$49.5 million in annual recurring revenue. The addressable market for the first year, targeting the Northeast corridor where the pilot is based, is conservatively 5,000 businesses.

5. Full System Architecture

The system is organized into five layers. Each layer has a single responsibility. No layer is aware of the internal workings of another — they communicate only through defined interfaces. This makes the system maintainable, testable, and replaceable piece by piece as the business grows.

Layer 1 — Channel Intake

The intake layer is responsible for receiving raw customer contact from every channel and converting it into a normalized event that the processing layer can consume. Each channel has a dedicated adapter.

- Phone calls are received by Twilio, which forwards the call to Vapi.ai using a webhook. Vapi manages the voice session end to end — speech to text, AI conversation, text to speech, and call state. When the order is confirmed, Vapi fires a webhook containing the structured result.
- WhatsApp and SMS messages are received by Twilio and forwarded via webhook to the n8n orchestration layer. Voice notes attached to WhatsApp messages are downloaded as audio files and sent to OpenAI Whisper for transcription before processing.
- All channel adapters produce the same output format: a raw intake event containing the channel type, customer phone number, message content or transcript, and the business ID derived from which Twilio number was contacted.

Layer 2 — AI Processing

The AI processing layer takes a raw intake event and produces a structured order object. For live phone calls, this layer is embedded inside Vapi — the AI converses in real time, handles clarifications, and closes the order. For text and voice note channels, this layer is a GPT-4o call with a structured prompt containing the business menu.

The system prompt for the AI contains the full menu of the specific business, including all items, standard ingredients, available modifications, unavailable modifications, pricing hints, and the business name used for greeting. The AI is instructed to ask clarifying questions when an order is ambiguous, to confirm the complete order before submitting, and to return a structured JSON object as its final output.

```
{ "items": [{ "name": "Michelangelo", "qty": 1, "mods": ["extra  
provolone", "no cherry peppers"] }], "customer_phone": "+12035550199",  
"channel": "phone", "business_id": "uuid" }
```

Layer 3 — Orchestration (n8n → Python/FastAPI)

n8n handles orchestration during the prototype and pilot phase. It receives webhooks from Vapi and Twilio, routes them through the AI processing step for text channels, writes confirmed

orders to Supabase, triggers customer confirmation SMS, and handles the ready notification flow. Every workflow in n8n is stateless — it processes one event and exits.

When the platform reaches 10 or more paying businesses, n8n is replaced by a Python FastAPI backend. The API handles all webhooks, manages session state for ongoing conversations, queues async jobs via Celery for SMS delivery and analytics, and exposes the REST endpoints used by the admin portal. The transition from n8n to FastAPI happens with zero change to the database schema or the frontend — only the orchestration layer is replaced.

Architecture rule: one ingestion pipeline, one order schema, one dashboard. Never build separate systems per channel.

Layer 4 — Data Layer

Supabase (PostgreSQL) is the database throughout all phases. It stores businesses, menus, orders, transcripts, staff users, and audit logs. Supabase real-time subscriptions power the kitchen display — the React app subscribes to the orders table and receives a push notification the instant a new row is inserted, with no polling required. Redis is added in the production phase for session state during active phone calls and for rate limiting.

Layer 5 — Presentation

Two frontend applications are built in React with Next.js. The kitchen display is a full-screen, high-contrast application designed to be read from across a room. The admin portal is a standard dashboard interface. Both are hosted on Vercel and communicate with Supabase directly for real-time data and with the FastAPI backend for management operations. In the prototype phase the admin portal is replaced by direct Supabase access.

6. Full Tech Stack

Layer	Tool	Purpose	Phase
Voice Agent	Vapi.ai	Phone call AI — speech, conversation, TTS	1
Telephony / SMS	Twilio	Phone numbers, SMS, WhatsApp API	1
Transcription	OpenAI Whisper	Voice note audio to text	1
Order AI	GPT-4o (OpenAI API)	Menu understanding, order extraction, chat	1
Orchestration (v1)	n8n Cloud	Webhook routing and workflow automation	1–2
Database	Supabase (PostgreSQL)	Orders, menus, businesses, real-time push	1+
Real-time	Supabase Realtime	Live kitchen display updates without polling	1+
Kitchen Display	React + Next.js	Full-screen order board for staff	1
Frontend Hosting	Vercel	Zero-config deployment for React apps	1+
API Backend (v2)	Python + FastAPI	Webhook handling, business logic, admin APIs	3+
Cache / Session	Redis	Active call state, rate limiting, retries	3+
Async Jobs	Celery + Redis	SMS delivery, transcription jobs, analytics	3+
Auth	Clerk	Business and staff login, multi-tenant sessions	3+
File Storage	AWS S3	Audio recordings, transcripts, menu images	3+
Error Monitoring	Sentry	Runtime error tracking and alerting	2+
Product Analytics	PostHog	Feature usage, funnel analysis, session replay	3+
Billing	Stripe	Monthly subscriptions, usage-based billing	3+
Hosting (v2)	Railway → AWS	FastAPI backend and workers, production-grade	3+

7. Database Schema

The schema is designed for multi-tenancy from the beginning. Every table that contains business-specific data includes a `business_id` foreign key. Row-level security policies in Supabase enforce that a business can only read and write its own data.

7.1 businesses

Column	Type	Description
id	UUID PRIMARY KEY	Unique identifier, auto-generated
name	TEXT NOT NULL	Display name shown to customers and on display
slug	TEXT UNIQUE	URL-safe identifier e.g. provenos-deli
phone_number	TEXT UNIQUE	Their Twilio inbound phone number
whatsapp_number	TEXT	Their Twilio WhatsApp number
ai_system_prompt	TEXT	Full GPT-4o system prompt with menu embedded
menu	JSONB	Structured menu — items, mods, prices, aliases
prep_time_minutes	INTEGER DEFAULT 15	Default ETA told to customers
business_hours	JSONB	Open/close times per day of week
timezone	TEXT	IANA timezone string e.g. America/New_York
is_active	BOOLEAN DEFAULT true	Enables or suspends the business on the platform
created_at	TIMESTAMPTZ	Onboarding timestamp

7.2 orders

Column	Type	Description
id	UUID PRIMARY KEY	Unique order identifier
business_id	UUID REFERENCES businesses	Which business this order belongs to
order_number	INTEGER	Human-readable sequential number per business

channel	TEXT	phone whatsapp_text whatsapp_voice sms
customer_phone	TEXT	E.164 format phone number for notifications
items	JSONB NOT NULL	Array of order items — see 7.5 for structure
raw_transcript	TEXT	Full conversation or message content
special_instructions	TEXT	Free-text note captured from customer
status	TEXT DEFAULT pending	pending accepted making ready done cancelled
notified_received	BOOLEAN DEFAULT false	Whether order confirmation SMS was sent
notified_ready	BOOLEAN DEFAULT false	Whether ready-for-pickup SMS was sent
placed_at	TIMESTAMPTZ	When the order was captured by the AI
accepted_at	TIMESTAMPTZ	When staff acknowledged the order
completed_at	TIMESTAMPTZ	When staff marked the order done

7.3 businesses_staff

Column	Type	Description
id	UUID PRIMARY KEY	
business_id	UUID REFERENCES businesses	
user_id	TEXT	Clerk user ID
role	TEXT	owner manager staff
created_at	TIMESTAMPTZ	

7.4 transcripts

Column	Type	Description
id	UUID PRIMARY KEY	

order_id	UUID REFERENCES orders	Links to the order this call produced
business_id	UUID REFERENCES businesses	
channel	TEXT	Which channel this transcript is from
content	TEXT	Full verbatim transcript or message thread
audio_url	TEXT	S3 URL of the audio file if applicable
created_at	TIMESTAMP TZ	

7.5 JSONB Order Item Structure

Each element of the items array in the orders table has the following shape:

```
{ "name": "Michelangelo", "qty": 2, "unit_price": 12.50, "mods": [{  
  "type": "add", "item": "extra provolone" }, { "type": "remove", "item":  
  "cherry peppers" }], "notes": "toasted please" }
```

7.6 JSONB Menu Structure (in businesses.menu)

```
{ "categories": [{ "name": "Hot Subs", "items": [{ "id": "micro-001",  
  "name": "Michelangelo", "aliases": ["mike", "mick"], "description":  
  "Chicken cutlet, fresh mozzarella, roasted peppers", "price": 12.50,  
  "default_mods": ["fresh mozzarella", "roasted peppers", "hot sauce"],  
  "available_adds": ["extra cheese", "banana peppers", "bacon"],  
  "available_removes": ["hot sauce", "roasted peppers"],  
  "available_substitutes": [{ "from": "fresh mozzarella", "to":  
    ["provolone", "american", "no cheese"] }] }] }] }
```

8. API Route Design (FastAPI — Phase 3+)

These routes are built in FastAPI in Phase 3 when n8n is replaced. In Phase 1 and 2, n8n handles all webhook routing and Supabase is accessed directly from the frontend.

8.1 Webhook Routes (called by Twilio and Vapi)

Method + Path	Caller	Description
POST /webhooks/vapi/order-complete	Vapi.ai	Receives confirmed order from phone call agent
POST /webhooks/twilio/whatsapp	Twilio	Receives inbound WhatsApp message or voice note
POST /webhooks/twilio/sms	Twilio	Receives inbound SMS
POST /webhooks/twilio/voice	Twilio	Receives inbound call — redirects to Vapi

8.2 Order Routes

Method + Path	Auth	Description
GET /orders	Staff	List orders for the authenticated business, filterable by status and date
GET /orders/:id	Staff	Single order with full items, mods, transcript link
PATCH /orders/:id/status	Staff	Update status — accepted, making, ready, done, cancelled
GET /orders/:id/transcript	Staff	Full transcript or message thread for the order

8.3 Business Management Routes

Method + Path	Auth	Description
GET /business	Owner	Get business profile, numbers, hours
PATCH /business	Owner	Update business name, prep time, hours

GET /business/menu	Owner	Fetch structured menu JSON
PUT /business/menu	Owner	Replace full menu — triggers AI prompt regeneration
POST /business/menu/import	Owner	Upload menu photo — AI extracts and structures it
GET /business/analytics	Owner	Call volume, captured orders, peak hours, top items
GET /business/staff	Owner	List staff users and roles
POST /business/staff	Owner	Invite a staff member by email

8.4 Admin Routes (ResurgeX operator only)

Method + Path	Auth	Description
GET /admin/businesses	Admin	List all businesses on the platform
POST /admin/businesses	Admin	Create and onboard a new business
PATCH /admin/businesses/:id	Admin	Update any business config
DELETE /admin/businesses/:id	Admin	Suspend or remove a business
GET /admin/analytics	Admin	Platform-wide metrics across all businesses

9. Voice Agent Design (Vapi.ai)

9.1 Agent Behavior

The Vapi voice agent is the most critical component of the system. It is the first thing every phone customer interacts with. Its behavior must feel natural, competent, and fast. The following rules govern the agent:

- Answer within two rings. Greet the caller by the business name immediately.
- Speak naturally at a moderate pace. Do not sound robotic. Do not over-explain.
- When a customer orders an item, repeat it back with the modifications before moving on.
- If an item is unclear or not on the menu, ask one specific clarifying question — not an open-ended question.
- After all items are captured, read back the complete order and ask for confirmation.
- If the customer confirms, end with the prep time and a friendly close. Do not extend the call.
- If the customer does not confirm or makes a correction, adjust the order and re-confirm.
- Never make up menu items. Never invent prices. If uncertain, ask.

9.2 System Prompt Structure

The Vapi system prompt is generated automatically when a business uploads or updates their menu. It has four sections:

1. Identity — who the agent is, what business it represents, the greeting format
2. Menu — the complete structured menu in a format the model reads reliably, including aliases
3. Rules — the behavioral rules above, plus business-specific rules like hours and pickup instructions
4. Output — instructions for how to format and submit the final order JSON via the Vapi end-call webhook

The system prompt is stored in `businesses.ai_system_prompt` and regenerated every time the menu changes.

9.3 Call Flow

1. Incoming call	Twilio receives the call. Webhook fires to FastAPI (or n8n in Phase 1). System looks up which business owns this number.
2. Route to Vapi	FastAPI instructs Twilio to connect the call to the Vapi assistant ID for this business. Vapi takes over the call.

3. Greeting	Vapi answers: 'Thank you for calling [Business Name], what can I get for you today?'
4. Order taking	Customer orders items. Agent confirms each one. Handles modifications and clarifications.
5. Order confirmation	Agent reads back the full order: 'Just to confirm — one Michelangelo, extra provolone, no cherry peppers. Is that right?'
6. Close	Customer confirms. Agent: 'Perfect, your order will be ready in about 15 minutes. See you soon!' Call ends.
7. Webhook fires	Vapi fires the end-call webhook to FastAPI with the structured order JSON.
8. Order written	FastAPI writes the order to Supabase. Kitchen display card appears. Confirmation SMS sent to customer.

10. Kitchen Display Screen

10.1 Design Principles

The kitchen display is used by people who are physically making food. It must be readable from across a counter, operable with one tap, and reliable with no loading states. Design principles:

- High contrast — dark background, large white text, colored status badges
- No login required in the kitchen — the display URL is unique to the business and always-on
- Sound alert on every new order — audible ping even if staff are not looking at the screen
- Order age timer — shows how many minutes since the order was placed, turns red after threshold
- One-tap Done — large button, no confirmation dialog, immediate feedback

10.2 Order Card Information

Each order card on the display shows:

- Order number — large, prominent, used to call out to the customer
- Channel badge — Phone / WhatsApp / SMS
- Every item with all modifications listed clearly below each item
- Special instructions if any
- Time since order was placed with color coding (green < 10min, yellow 10–20min, red > 20min)
- Accept button (moves to Making status) and Done button

10.3 Status Flow on Display

New	Order just arrived. Alert sound plays. Card appears at top of screen.
Accepted	Staff tapped Accept. Signals they have seen the order and are working on it.
Making	Active preparation in progress.
Ready	Staff tapped Done. Customer receives SMS notification. Card moves to completed column.
Picked Up	Staff or customer confirms pickup. Order archived.

11. Customer Notification Messages

Order Received (SMS)	Hi! Your order at [Business Name] has been received. Order #[number]. Ready in approximately [prep_time] minutes. We will text you when it is ready.
Order Ready (SMS)	Your order #[number] at [Business Name] is ready for pickup!
Order Received (WhatsApp)	Same content as SMS but sent via WhatsApp if the order came through WhatsApp.
Missed Call Recovery	Hi, we missed your call at [Business Name]. Reply here to place your order by text, or call back at [number].

Missed call recovery is a Phase 2 feature. When a call is not answered by the AI (e.g. the system is briefly unavailable), Twilio triggers a webhook and an automatic text is sent to the caller.

12. Multi-Tenancy Design

Every component of the system is designed for multi-tenancy from the beginning. The rule is: one Twilio number per business, one Vapi assistant per business, one menu per business, one kitchen display URL per business, one Supabase row-level security policy per business.

12.1 How Business Isolation Works

- Every inbound call or message arrives on a specific Twilio number. The system uses that number to look up the `business_id`.
- The Vapi assistant for each business is configured with that business's menu and system prompt only. There is no shared assistant.
- All database queries include a `WHERE business_id = ?` clause. Supabase RLS policies enforce this at the database level so a bug in the application layer cannot leak data across businesses.
- The kitchen display URL is `/display/:business_slug` — unique to each business. No authentication required on the display itself.
- The admin portal requires Clerk authentication. A staff user can only access the business they are assigned to. The ResurgeX operator account can access all.

12.2 Onboarding a New Business

5. ResurgeX creates a new business record in the admin portal
6. A Twilio phone number is provisioned and assigned to the business
7. The business owner uploads their menu — photos or a typed list
8. The AI menu parser extracts structured JSON from the menu
9. The Vapi system prompt is auto-generated from the menu JSON
10. A Vapi assistant is created via the Vapi API with that system prompt
11. The Twilio number is configured to forward calls to that Vapi assistant
12. The kitchen display URL is shared with the business — they open it on any browser
13. Test call is made to confirm the full pipeline is working
14. Business is live — go-live typically under one hour from menu upload

13. Build Roadmap

Primary channel is phone calls. Build the voice agent in Week 1, not Week 3.

Phase 1 — Working Phone Agent (Week 1–2)

Goal: A real phone call can be made to a test number, the AI answers as Provenos, takes an order, and the order appears on a kitchen display screen. This is the demo that sells everything else.

15. Supabase project created — businesses and orders tables deployed
16. Provenos menu photos uploaded — AI extracts and structures menu.json
17. Vapi assistant created with Provenos system prompt and menu
18. Twilio test number provisioned and connected to Vapi assistant
19. n8n webhook workflow: Vapi order complete → Supabase write → Twilio SMS
20. Kitchen Display v1 built in React — live order cards via Supabase Realtime
21. End-to-end test: call number → AI takes order → card on screen → confirmation SMS

Phase 2 — Text Channels + Polish (Week 3–4)

Goal: WhatsApp text and voice notes also route into the same pipeline. The full Provenos experience is production-ready. A second test customer is found.

22. n8n WhatsApp webhook workflow built and tested
23. OpenAI Whisper integration for voice note transcription
24. Kitchen display polished: sound alert, order age timer, status transitions
25. Ready notification SMS implemented
26. Missed call recovery SMS implemented
27. Full edge case testing: unclear orders, multiple items, mid-order corrections
28. Provenos pilot goes live
29. 60-second demo video recorded for sales use

Phase 3 — Production Backend (Month 2)

Goal: Replace n8n with Python FastAPI. Add authentication. Add error monitoring. The system is stable enough for 10 paying businesses.

- 30. FastAPI project scaffolded with all webhook routes
- 31. Celery + Redis for async SMS jobs and transcription retries
- 32. Clerk authentication integrated for admin portal
- 33. Sentry error monitoring live
- 34. Automated Vapi assistant creation on business onboarding
- 35. Admin portal v1: menu editor, order history, basic analytics
- 36. 5 paying businesses onboarded

Phase 4 — SaaS Product (Month 3)

Goal: Self-serve onboarding. A business owner can sign up, upload their menu, and be live without any help from ResurgeX.

- 37. Self-serve signup flow with Stripe subscription
- 38. Menu upload with AI parsing — no manual intervention
- 39. PostHog product analytics installed
- 40. Multi-location support — one business account, multiple numbers and displays
- 41. 10 paying businesses, path to 50 clearly mapped

Phase 5 — Scale (Month 4–6)

Goal: 50 businesses. \$5K MRR. Product running independently.

- 42. Multilingual voice agent support
- 43. POS sync integrations (Square, Clover)
- 44. Payment link in confirmation SMS
- 45. Loyalty and repeat-customer recognition
- 46. Delivery routing for businesses offering delivery
- 47. Franchise and multi-location enterprise tier

14. Revenue Model

Plan	Price	What's Included
Starter	\$49 / month	Up to 150 orders/month. Phone AI agent only. 1 kitchen display. SMS notifications. Basic order history.
Growth	\$99 / month	Unlimited orders. All channels (phone, WhatsApp, SMS). 1 kitchen display. Analytics dashboard. Transcripts. Menu editor.
Pro	\$149 / month	Everything in Growth. Multiple display screens. Multi-location support. Staff roles and permissions. Priority support. Custom AI persona.
Enterprise	Custom	White-label option. Dedicated support. Custom integrations. SLA guarantees. Franchise management.

Cost structure per business on the Growth plan: Twilio number \$1/month, Vapi usage approximately \$8–15/month at average deli call volume, OpenAI API calls approximately \$3–5/month, Supabase and infrastructure approximately \$2/month per business. Gross margin on the \$99 plan is approximately 75–80%.

50 businesses on Growth = \$4,950 MRR. This is the \$5K target. It requires signing one new business every 3–4 days for 6 months.

15. Go-To-Market Strategy

Step 1 — The Provenos Demo (Week 2)

Get the system live at Provenos. Record a 60-second video: a phone call comes in, the AI answers as Provenos, takes the order, the kitchen screen lights up with the order card, and the customer gets a text. That video is the entire pitch. Every other business owner who sees it immediately understands the value.

Step 2 — Direct Local Outreach (Month 1)

Walk into 20 delis and sandwich shops in Connecticut and New York with the demo video. The pitch is one sentence: your phone answers itself, the order goes straight to your kitchen screen, your staff just makes the food. Ask for \$99 a month. Close 5 in the first month.

Step 3 — LinkedIn Content (Ongoing)

Post the demo video on LinkedIn. Document the build in public — short posts about the problem, the solution, and real results from Provenos. Business owners share these posts within their communities. Developers share them within theirs. Both audiences matter.

Step 4 — Self-Serve Onboarding (Month 3)

Once the product is stable with 5 customers, remove the human from onboarding. A business owner finds the website, enters their details, uploads their menu photo, pays by card, and is live in 30 minutes. This is when growth becomes possible without proportional effort.

Step 5 — Partnerships (Month 4+)

Reach out to local business associations, food industry groups, and small business consultants who work with the target customer. A single partnership that refers 10 businesses per month is worth more than 10 individual sales calls.

16. What We Build First — Starting Now

Upload the menu photos. That is the single input needed to start building everything below.

When the menu is uploaded, this is the exact sequence of work:

48. AI parses the menu photos into structured menu.json — every item, ingredient, modification option, and alias
49. Supabase project created — businesses and orders tables deployed with the schema from Section 7
50. Vapi assistant created with the Provenos system prompt generated from the menu
51. Twilio account opened — free trial number provisioned and connected to Vapi
52. n8n webhook workflow built: Vapi end-call → parse order → write to Supabase → send confirmation SMS
53. Kitchen Display built in React — subscribes to Supabase in real time, renders order cards, Done button
54. End-to-end test: call the Twilio number, AI answers as Provenos, place an order, confirm card on screen and SMS

The problem is real. The market is underserved. The pilot customer is next door.

Upload the menu. We start building today.

ResurgeX Technologies · OrderFlow AI · Blueprint v2.0
